LIDDING STRUCTURE

This invention relates to a lidding structure and, in particular, to a method of making a peelable lidding structure for use in the closing of food cans, for example.

5 Easy open ends using a ring pull tab for removal of a centre panel by tearing a score, are well established for use in the closing of cans, in particular those cans used for the packaging of pet food, soup and other food products. However, as food products typically require
10 processing to comply with food safety standards, this type of easy open end is relatively thick in comparison with the side wall of the can, in order to withstand the temperatures and pressures inherent in the process.

 Alternative closures which comprise a foil-type
15 lidding structure which is adhered to a metal ring which is, in turn, seamed to the edge of the can body, have also been proposed. The lidding structure typically comprises a laminate structure of polypropylene, aluminium and varnish. The polypropylene layer is used
20 for bonding to the metal ring. A tab which extends laterally from a centre panel of the lidding structure can be folded over the centre panel during retorting, or during handling operations such as seaming.

 The aluminium layer performs as a barrier material
25 and is generally about 60 to 70 microns thick. The thickness of this aluminium layer is not only dictated by the barrier requirements but also by the need to provide a "deadfold" to retain its folded position and prevent curling during sterilisation. This curling occurs at
30 retort temperatures, which are typically 120°C to 132°C

for processing products such as fish, pet foods or soup, due to differential shrinkage in layers which form the structure. The thick layer of aluminium thus retains the tab folded flat over the centre panel in particular
5 during processing and seaming.

Both of the above types of lidding structure are costly to manufacture, in particular due to the high costs of metal used.

According to the present invention, there is
10 provided a lidding structure for a container, the lidding structure including: a barrier layer for preventing the passage of fluids; and a tab extending from a centre panel of the lidding structure for removing the lidding structure from the container to allow access to the
15 container contents; in which the barrier layer includes less than 20 microns thickness of aluminium; and in which the tab is folded over the centre panel and secured in the folded position on the centre panel for processing of can contents and/or handling operations.

20 The lidding structure is particularly suitable for processed food applications. Material used for the lidding structure is flexible and has little "deadfold" (it cannot retain its folded position) due to the low thickness (or absence) of the aluminium layer. However,
25 by securing the tab in the folded position, the fold is retained independently of the structure, specifically its aluminium content. Curling during processes such as sterilisation is therefore avoided.

As the structure is flat and the tab is secured to
30 the centre panel, obstruction of tooling during processes

such as seaming is avoided. Usually, the structure is fixed to a "ring" which is then seamed to a container body. Securing the tab prevents disturbance of such a double seam.

5 Preferably, the aluminium layer is not more than 15 microns in thickness. The lidding structure may include one or more of the following layers: polyethylene terephthalate (PET), aluminium, nylon and/or polypropylene. These together form a structure which is
10 significantly lower in cost than currently available peelable closures.

Where a nylon layer is used, the barrier properties (impermeability to oxygen) prevent corrosion of the aluminium layer by contents of the container and may even
15 allow the structure to be used without any aluminium layer at all, with consequent cost savings. PET provides strength to the structure, and polypropylene is a heat sealable layer which may be used for securing the tab in its folded position.

20 Ideally, the tab may be secured in the folded position by an adhesive or by heat sealing. In this case, the tab or centre panel usually includes a patch, an area of which is exposed by a hole in the tab or centre panel respectively, and the tab is secured in the folded
25 position by the adhesive or heat sealing to the exposed area of patch. This patch may be a discrete piece of material, for example polypropylene for heat sealing, or it may be an outer part of the tab which is folded over a hole on an inner part of the tab.

According to another aspect of the present invention, there is provided a method of forming a lidding structure having a centre panel and a tab extending from the centre panel, the method comprising:

5 forming a hole in a portion of a lidding material corresponding to the centre panel of the lidding structure; covering the hole by fixing a patch to a first side of the lidding material, thereby forming an area of patch exposed by the hole on the opposite side of the

10 lidding material; cutting the lidding structure out of the lidding material; folding the tab portion of the lidding structure over the centre panel, thereby covering the exposed area; and securing the tab to the centre panel by heat sealing or bonding of the exposed region.

15 This inventive concept of heat sealing or bonding the tab to the centre panel in order to secure the tab in place for processing, seaming etc. can be achieved by alternative methods. Thus in one alternative aspect of the present invention there is provided a method of

20 forming a lidding structure having a centre panel and a tab extending from the centre panel, the method comprising: forming a hole in a portion of a lidding material corresponding to the tab of the lidding structure; covering the hole by fixing a patch to a first

25 side of the lidding material, thereby forming an area of patch exposed by the hole on the opposite side of the lidding material; cutting the lidding structure out of the lidding material; folding the tab portion of the lidding structure over the centre panel, so that the

30 exposed region is covered by the centre panel; and

securing the tab to the centre panel by heat sealing or bonding of the exposed area.

In a preferred embodiment, the hole may be formed in an inner part of the tab and the patch may then comprise an outer part of the tab portion of the lidding structure. The method ideally further comprises folding this outer part of the tab over an inner part of the tab, thereby covering the hole and forming the exposed area. As a result, extra rigidity in the form of a double thickness of tab material is provided to the tab prior to securing the tab to the centre panel.

Alternatively, the method may comprise folding an outer part of the tab over an inner part of the tab so that the patch is disposed between the outer and inner parts of the tab; and fixing the outer part of the tab to the inner part. This provides not just a double thickness of tab material but the layer of patch material between the tab layers.

Each method typically forms a lidding structure which includes a barrier layer using less than 20 microns of aluminium, preferably not more than 15 microns in thickness of aluminium. The lidding structure may include one or more of the following layers: polyethylene terephthalate (PET), aluminium, nylon and/or polypropylene. A varnish or other coating may also be used which avoids any requirement for PET to bond to polypropylene (which is not possible if these are in their "pure" form). The choice of these layers may mean that a barrier layer can be provided without any aluminium at all as discussed above.

Preferred embodiments of the invention will now be described, by way of example only, with reference to the drawings, in which:

Figure 1 is a perspective view of a lidding structure;

Figure 2 is a schematic view of a method of forming a lidding structure; and

Figure 3 is a schematic view of an alternative method of forming a lidding structure.

Figure 1 shows a basic flexible lidding structure 1 which has been fixed to a "ring" 2 for double seaming onto a container (not shown). The closure formed by the lidding structure and ring are typically intended for use in the packaging of fish, pet foods etc where an easy open end is desirable. Such products require processing in a retort at temperatures of typically 120°C to 132°C and this, together with the requirement of double seaming ring 2 to a the container, make securing of the tab imperative. Prior to the present invention, it has always been thought necessary to have a relatively thick layer of aluminium in the lidding structure in order that the tab 3 be held against centre panel 4 by the dead fold of the aluminium layer.

In the structure 1 of figure 1, adhesive between the tab 3 and centre panel 4 of the lidding structure 1, secures the tab through a hole 5 in the lidding. Different ways of achieving this bond will become apparent from the description of figures 2 and 3 which follow.

Figure 2a and 2b are different aspects of the same method which indexes a lidding material 6 from left to right as shown in the drawings and a strip of patch material 7 at an angle to the path of the lidding material.

As a first step A in the process, a hole 5 is formed in the lidding material 6 at a position which corresponds to a tab of the final lidding structure. A self-adhesive patch 8 which ideally includes a reinforced backing surface, is either punched out (figure 2a) or cut off (figure 2b) from the strip of patch material 7 and stuck to the tab position (B and C). The patch 8 is usually slightly larger than the size which the final tab of the lidding structure will be.

The lidding material with patch 8 is fed into a lid cutter and cut in conventional manner (step D) and sealed to a ring 2 to form the structure 1. Finally, the tab 3 is folded and stuck by adhesive on the patch 8 which is exposed by the hole 5. The final lidding structure is shown generally at position E.

Although this embodiment is described as using adhesive to secure the tab, it is clearly possible to secure the tab by heat sealing if a heat sealable layer such as polypropylene is provided on the lidding material and patch material. The important feature is that curling of the tab during thermal processing is prevented. This method requires no difficult folding and makes good use of material.

In the embodiment of figure 3, a lidding material 6 is indexed from left to right and a hole 5 punched in the

centre of the future tab (step A) in a similar manner to that shown in figure 2. This embodiment, however, does not require a separate strip of patch material. Instead, an outer part of the tab is used as a patch.

5 A U-shape is lanced or cut in a position corresponding to an outer part 10 of the tab, from the lidding material (step B) and the cut material folded down to around 90 degrees. Motion of the lidding index feed continues the folding process until the outer part
10 is completely folded over an inner part 11 of the tab.

 If the lidding material includes a heat sealable layer, this can be used for bonding purposes. Alternatively, a small drop of glue can be applied to the underside of the lidding material, particularly if this
15 can be fed through the machine without touching machine components. The adhesive can be applied by various methods such as gravure printing. The use of hot melt adhesive means that the glue can be reactivated by reheating using a contact plate, by ultraviolet radiation
20 or by induction heating for example. The tab may be secured either prior to, during or after heat sealing to the ring. The heat seal may be used to reactivate adhesive if the lidding material includes a conductive layer. Finally, a combination of the patch process of
25 figure 2 and the tab folding of figure 3 can be used if extra rigidity of the tab is desirable. In the last case, patch material would be indexed and adhered to the underside of the tab.

 The lidding material is fed into a lid cutter and
30 cut in conventional manner (step D) and sealed to a ring

2 to form the structure 1. Finally, the tab 3 is folded
and stuck through the hole 5 by a heat seal layer of the
lidding material. Alternatively, the tab is secured by a
hot melt adhesive. The final lidding structure is show
5 generally at position E.

Although these methods and structures have all been
described with reference to a hole 5 which is formed in
the tab position, it is clearly possible for a hole to be
formed in the centre panel and the tab secured in the
10 same manner.

CLAIMS:

1. A lidding structure for a container, the lidding structure including:
 - a barrier layer for preventing the passage of fluids; and
 - a tab extending from a centre panel of the lidding structure for removing the lidding structure from the container to allow access to the container contents;
 - in which the barrier layer includes less than 20 microns thickness of aluminium;
 - and in which the tab is folded over the centre panel and secured in the folded position on the centre panel for processing of can contents and/or handling operations.
2. A lidding structure according to claim 1, in which the aluminium layer is not more than 15 microns in thickness.
3. A lidding structure according to claim 1 or claim 2, in which the lidding structure includes one or more of the following layers: polyethylene terephthalate (PET), aluminium, nylon and/or polypropylene.
4. A lidding structure according to any one of claims 1 to 3, in which tab is secured in the folded position by an adhesive or by heat sealing.

5. A lidding structure according to claim 4, in which the tab or centre panel includes a patch, an area of which is exposed by a hole in the tab or centre panel respectively, and the tab is secured in the folded position by the adhesive or heat sealing to the exposed area of patch.

6. A method of forming a lidding structure having a centre panel and a tab extending from the centre panel, the method comprising:

forming a hole in a portion of a lidding material corresponding to the centre panel of the lidding structure;

covering the hole by fixing a patch to a first side of the lidding material, thereby forming an area of patch exposed by the hole on the opposite side of the lidding material;

cutting the lidding structure out of the lidding material;

folding the tab portion of the lidding structure over the centre panel, thereby covering the exposed area; and

securing the tab to the centre panel by heat sealing or bonding of the exposed region.

7. A method of forming a lidding structure having a centre panel and a tab extending from the centre panel, the method comprising:

forming a hole in a portion of a lidding material corresponding to the tab of the lidding structure;

covering the hole by fixing a patch to a first side of the lidding material, thereby forming an area of patch exposed by the hole on the opposite side of the lidding material;

cutting the lidding structure out of the lidding material;

folding the tab portion of the lidding structure over the centre panel, so that the exposed region is covered by the centre panel; and

securing the tab to the centre panel by heat sealing or bonding of the exposed area.

8. A method according to claim 7, in which the hole is formed in an inner part of the tab and the patch comprises an outer part of the tab portion of the lidding structure, the method further comprising folding the outer part of the tab over an inner part of the tab, thereby covering the hole and forming the exposed area.

9. A method according to claim 7, further comprising:
folding an outer part of the tab over an inner part of the tab so that the patch is disposed between the outer and inner parts of the tab; and
fixing the outer part of the tab to the inner part.

ABSTRACT

LIDDING STRUCTURE

A peelable lidding structure particularly for use in the closing of food cans has a tab which is folded over the centre panel and secured in the folded position for processing of can contents and/or handling operations. As the tab is secured, an inexpensive laminate structure which requires little or no aluminium content can be used. Methods of forming the lidding structure include exposing a layer of heat sealable material or an adhesive layer so that the tab can be folded over and adhered to this layer, for example by heat sealing.
